TASK 4 Data Visualization and Storytelling

Data Analytics Internship | Veda Technology

1. Introduction

This project focuses on using data visualization and storytelling to turn structured retail data into understandable business insights. Power BI Desktop is used to create charts that help explore sales performance, profit, product categories, regions, and changes over time.

2. Objective

The main objective is to build a clear visual narrative that answers the business question: “How can a retail business understand its sales and profitability to make better decisions?” The report organizes visualizations in a logical sequence and pairs each visual with a concise takeaway.

3. Dataset

The project uses the Sample Superstore dataset in Excel format. The Orders table is the primary table for analyzing fields such as Order Date, Sales, Profit, Category, Sub-Category, and Region. The dataset file used in this project is named Sample-Superstore.xlsx (the exact downloaded filename may vary).

4. Tools Used

Power BI Desktop — to import data and build visualizations.

Microsoft PowerPoint — to prepare a presentation-style visual story.

GitHub — to store and share project files and documentation.

5. Methodology

Imported the Sample Superstore Excel workbook into Power BI.

Selected the Orders table as the main source for sales and profit analysis.

Checked the available fields and their data types before building charts.

Created visualizations to compare category sales, regional profit, monthly sales trends, and sub-category profitability.

Organized the charts into a narrative from overall performance to detailed findings and recommendations.

6. Visualizations and Their Purpose

Sales by Product Category: Compares total sales across categories and identifies which category contributes the most revenue.

Profit by Region: Compares profit across regions to identify differences in regional profitability.

Monthly Sales Trend: Shows how sales change over time and helps identify periods of growth, decline, or fluctuation.

Profit by Product Sub-Category: Highlights product groups with positive or negative profit for further investigation.

Sales by Region and Product Category: Compares regional sales and shows how each category contributes to the regional total.

7. Key Insights

The charts are designed to reveal differences in sales across categories, changes in monthly revenue, regional profit performance, and variation in profitability among product sub-categories. Specific highest/lowest categories, regions, and values should be recorded from the completed Power BI visuals. No numerical results are stated here because they must be verified against the actual charts.

8. Recommendations

Monitor monthly sales to identify notable changes and possible seasonal patterns.

Investigate sub-categories with low or negative profit, including their costs, pricing, and discount levels.

Compare regional sales and profit together rather than judging performance from sales alone.

Use category-level results to support inventory planning and sales priorities.

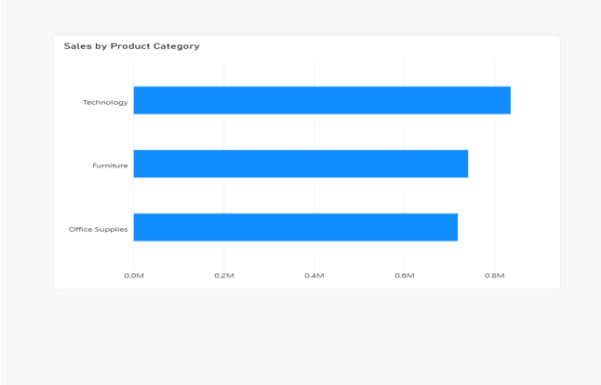

Review the visual story periodically as new data becomes available.

9. Conclusion

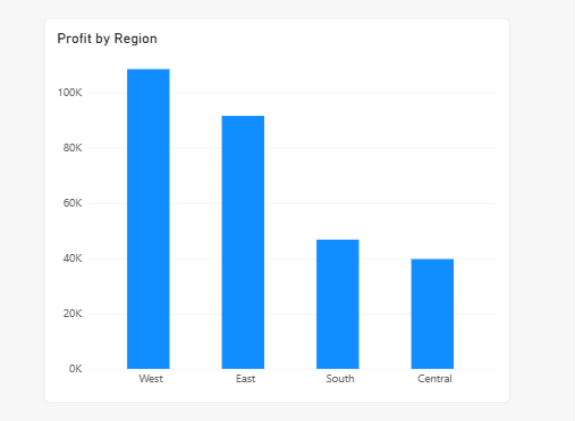

This project demonstrates how Power BI visualizations can make retail data easier to understand. By presenting sales, profit, time trends, and regional and product comparisons in a logical sequence, the report supports evidence-based discussion and business decision-making. The final narrative should include verified observations from the completed charts.

10. Data Visualization and Storytelling

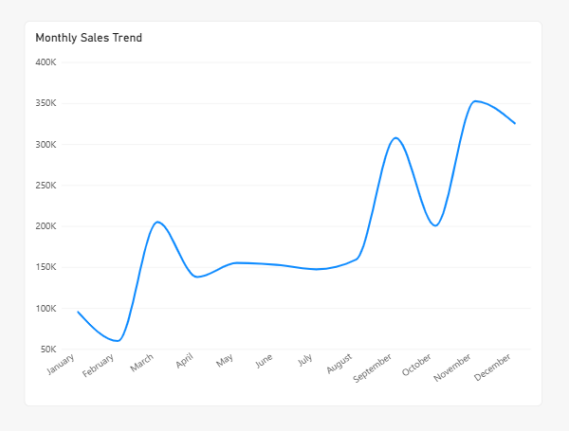

1.Sales by Product category

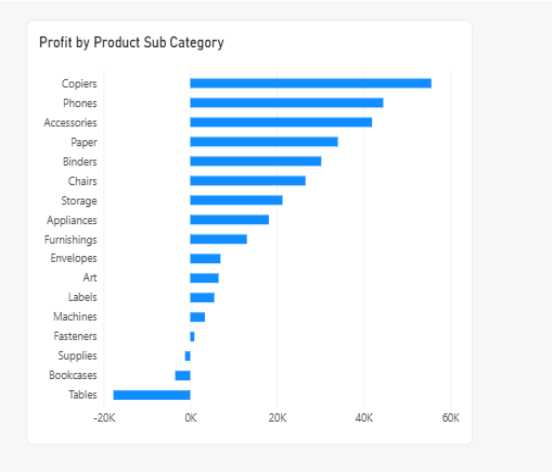

2.Profit by Region

3.Monthly Sales Trend

4.Profit by Product sub-Category

5.Sales by Region and Product Category
